What is thin-film solar technology?

Thin-film solar technology represents a departure from traditional silicon-based solar panels. Instead of using thick layers of crystalline silicon, thin-film solar cells are made by depositing one or more thin layers of photovoltaic material onto a substrate.

How much does a thin-film photovoltaic cost?

LCOE modeling: CdTe \$38 to \$65/MWh; CIGS high \$50s; perovskite/Si \$40 to \$45/MWh. Thin-film photovoltaics offer pathways to scalable, low-cost, and unconventional applications of solar energy. The established thin-film technologies include amorphous silicon (a-Si), cadmium telluride (CdTe), and copper indium gallium selenide (CIGS).

How are thin-film solar cells made?

Instead of using thick layers of crystalline silicon, thin-film solar cells are made by depositing one or more thin layers of photovoltaic material onto a substrate. These layers are incredibly thin - often just a few micrometers thick, which is about 100 times thinner than traditional solar cells.

How do thin-film solar panels work?

However, in terms of how they work, thin-film solar panels are no different from their traditional counterparts. Like silicon wafers, the semiconductor material layered on top of the substrate uses the photovoltaic effect to convert light energy into electrical energy.
